LONG-TERM GOALS

Our research group, under PI Thea Bechshøft, has recently shown that it is possible to extract and measure cortisol in cetacean skin (Bechshoft et al. Submitted). The goal of the current project is to validate this novel method by measuring baseline cortisol levels in cetacean skin and demonstrating the correlation between an acute stress exposure and the ensuing skin cortisol response.

OBJECTIVES

At the conclusion of the project period, we expect to have provided a greater understanding of a) the relationship in cetaceans between blood cortisol levels and skin cortisol levels, b) the period of time it takes before an acute stress response is measurable in the cetacean skin matrix, and c) cetacean baseline cortisol levels in skin, as well as inter- and intra-individual fluctuations.

APPROACH

The project is executed under PI Dr. Thea Bechshoft, in collaboration with Dr. Dorian Houser (National Marine Mammal Foundation, USA), Dr. Bjarne Styrishave (Copenhagen University, Denmark), and Dr. Andrew J. Wright (George Mason University, USA and Aarhus University, Denmark).

The project will validate the recently developed skin cortisol analysis method (Bechshoft et al. Submitted) using skin samples collected from bottlenose dolphins (*Tursiops truncatus*). The dolphins will be sampled as part of an ongoing out-of water stress test and stress hormones study conducted by Dr. Dorian Houser in collaboration with the U.S. Navy Marine Mammal Program (MMP) under ONR project N000141110436. The stress test in brief: Each dolphin is asked to perform a routine, voluntary beach into a padded beaching tray. Immediately following beaching, a needle is inserted into the peduncle of the dolphin and blood is collected every 15 minutes for two hours, in addition to other manipulations (e.g. blubber biopsies). This process has shown to significantly raise both cortisol and aldosterone above baseline conditions and thus equals an acute stress response. The stress test will be followed by sampling from various matrices over a longer period of time. For the skin cortisol validation project, non-invasive skin samples will be collected from a total of five animals at three

points in time: pre-stress test, at time of the stress test, and post-stress test. The results of the stress test will determine the link between the level of cortisol in the blood and the skin of bottlenose dolphins. The results will also establish the delay between a spike in blood cortisol levels and any corresponding spike in skin cortisol levels, thus helping to validate the use of skin cortisol to assess chronic stress levels in bottlenose dolphins and other cetaceans. All skin samples will be analyzed for cortisol levels at the University of Copenhagen, Denmark (Bechshoft et al. Submitted).

WORK COMPLETED

The bottlenose dolphin stress tests are proceeding as scheduled. All sampling, including post-stress test skin collection, is expected to be finished by January 2015, after which the samples will be shipped to Denmark for analysis.

RESULTS

Bottlenose dolphin stress tests are currently ongoing. All sampling, including post-stress test skin collection, is expected to be finished by January 2015, after which chemical lab analysis and statistical data analysis will ensue.

IMPACT/APPLICATIONS

A validated method for assessing cortisol in non-invasively collected cetacean skin samples will bring new possibilities for stress assessment in cetaceans, opening up a new avenue of research in physiological response studies following exposure to stressors. The current study will provide the validation of this novel method (Bechshoft et al. Submitted) by measuring basal level cortisol in cetacean skin and demonstrating the correlation between an acute stress exposure and the ensuing skin cortisol response.
